

Title: Credit System Overview Credit scoring is a critical component of modern financial systems. A credit score represents an individual's creditworthiness and is widely used by lenders, financial institutions, and even employers in some contexts. Scores typically range from 300 to 850, with higher scores indicating lower risk. The calculation of credit scores involves multiple factors. Payment history is the most significant, accounting for approximately 35% of the score. This includes whether payments are made on time and whether there are any delinquencies. Credit utilization, which measures how much of available credit is being used, contributes around 30%. Experts recommend keeping utilization below 30%, though some lenders prefer it under 25%. Another important factor is the length of credit history. A longer history provides more data points and generally improves the score. Credit mix, including credit cards, mortgages, and installment loans, also plays a role. New credit inquiries, especially hard inquiries, can temporarily lower the score. Financial institutions often have their own internal policies layered on top of general credit scores. For example, while a score of 680 may be acceptable for loan approval, preferred rates are usually offered to those with scores above 740. Some lenders may approve applicants with lower scores if they demonstrate stable income and employment history. Conflicting guidelines may exist across different institutions. One policy might emphasize a utilization threshold of 25%, while another accepts up to 30%. Similarly, definitions of "excellent" credit can vary, with some sources citing 750 and others 800 as the benchmark. For users building AI systems around financial documents, it is essential to reconcile such variations. Systems must identify authoritative sources, consider recency, and validate information across multiple documents. This ensures that answers generated for end users are both accurate and trustworthy. In summary, credit scoring is not a single fixed formula but a combination of statistical models, institutional rules, and contextual interpretation. Any system designed to answer questions about credit must incorporate hybrid retrieval, conflict resolution, and strong grounding mechanisms.
